Git Commands

Introduction

When you install Git-bash, the first thing you should be doing is setting up your user details as follows only one time.

```
#git config --global user.name "DevOps Training Bangalore"
#git config --global user.email devopstrainingblr@gmail.com
```

Checking for settings

#git config --list

You can also check what Git thinks a specific key's value is by typing git config <key>:

#git config user.name

Task 1: Create the git local repository in local machine (Laptop/Desktop), add one file (DBConnect.java) and update that file, create the github remote repository (https://github.com) and move the local code to github repository.

Go the directory where you want to create the git repository.

```
# cd ~/Desktop
# mkdir git-practice-commands
                              echnologies?
#cd git-practice-commands
#git init: Create a local Git empty repository.
```

Initialized empty Git repository in /Users/MithunReddy/git/git-practice-commands/.git/

#git status: Gives the status of your untracked files.

#touch DBConnect.java

#git status

#vim DBConnect.java

#git add DBConnect.java: Add the files(here DBConnect.java) into your staging area.

#git status

On branch master

Initial commit

Changes to be committed:

(use "git rm --cached <file>..." to unstage)

new file: DBConnect.java

Git Commands

#git status

On branch master

nothing to commit, working tree clean

> Open the file (DbConnect.java) and update with some text.

#vim DBConnect.java

#git commit -a -m "Updated DBConnect.java file": If we use -a along with commit command, no need to execute git add command.

[master 7f795a7] Updated DbConnect.java file

1 file changed, 1 insertion(+)

> Create the repository in github as follows.

Login into github (http://github.com)

On right side top corner click on "+" symbol and click on "New repository" and give the Repository name and click on Create repository,

#git remote add origin git@gitbub.com:devopstrainingblr/test.git: Adding the URL for the remote repository where your local repository code will be pushed.

git remote –v :

#git remote show origin: It will give the information on a particular remote (here origin is the remote name)

git remote remove origin: It will remove the remote origins.

#git push origin master: Push the changes in your local repository to GitHub remote repository. (Here push is the git command, origin is the remote name and master is the branch name)

Counting objects: 6, done.

Delta compression using up to 4 threads. Compressing objects: 100% (2/2), done.

Writing objects: 100% (6/6), 479 bytes | 0 bytes/s, done.

Total 6 (delta 0), reused 0 (delta 0)

To git@github.com:devopstrainingblr/test.git

* [new branch] master -> master

Branch master set up to track remote branch master from origin.

#git status

On branch master

Your branch is up-to-date with 'origin/master'. nothing to commit, working tree clean

#git log: It will give all commit ids.

#git show --pretty="" --name-only << Commit ID >> : It will display all the files which are

http://mithuntechnologies.com

devopstrainingblr@gmail.com

Git Commands

committed in that particular commit.

#git clean -n: It will preview the changes.

#git clean -f: If we want to remove new files from working area.

#git reset << File Name>> : To untrack the tracked files (revert back to working area from staging area.).

#git revert << Commit ID>> : It will revert the changes committed in that particular commit id from local repo.

#git push origin master -f: It will revert the changes from remote repo.

Branches

#git branch : It gives the branch names in current repository. **#git branch bugfix :** It will create the bugfix branch in local git repository.

#git branch -v: It will display all the branches in your repo, and also tell you what branch you're currently in.

bugfix 87226db initial commit

* master 87226db initial commit

Note: Here * indicate currently in use branch.

git checkout bugfix: Switch to bugfix branch.

Switched to branch 'bugfix'

Update the Bhaskar.txt like change bugfix branch # git add .: Add one or more files to staging

git commit -m "bugfix commit"

git checkout master: Switch to master branch.

Switched to branch 'master'

Updat the Bhaskar.txt like change 3 – master branch

git add.

git commit -m "master commit"

git checkout bugfix : Switch to bugfix branch.

Switched to branch 'bugfix'

Check the file and see the contents in file.

#git checkout master

#git diff master bugfix

mologies

Git Commands

#git merge bugfix

Fix the conflicts

#git add.

#git commit -m "merging"

#git push origin --all: Push all branches code to your remote repository.

#git branch -d bugfix: Deletes the bugfix branch in local repo.

#git push origin : bugfix (OR) git push origin --delete bugfix: It will delete a remote branch in the repository.

Tags

git tag: It will dipslays the tags.

git tag << Tag Name>> : It will create the tag.

git push origin -- tags: It will push the tag into remote repo.

Note: Tags are not automatically pushed when you push a branch or use the --all option. The -- tags flag sends all of your local tags to the remote repository.

git tag -d << Tag Name>> : It will delete the tag.

\$ git push wallmart master
fatal: unable to access 'https://github.com/mithuntechnologiesnew/wallmart.git/'
: SSL certificate problem: self signed certificate in certificate chain

When you get the above error while committing the code from local repository to remote repository execute the following command in git bash 2 6 5

git config --global http.sslVerify false

Steps for Code Checkout into local from Repository

Go to the directory where we need to commit the code/checkout the code cd C:\MithunTecnologies\JavaWorkspace\MTWorkSpace

Get the code from Git Repository as follows.

git clone <<GitHub URL>>

What is the difference between git fetch and get pull?

Ans) git fetch: It will get the update from git remote repo and will update your local repo. But it will not merge with Local working copy.

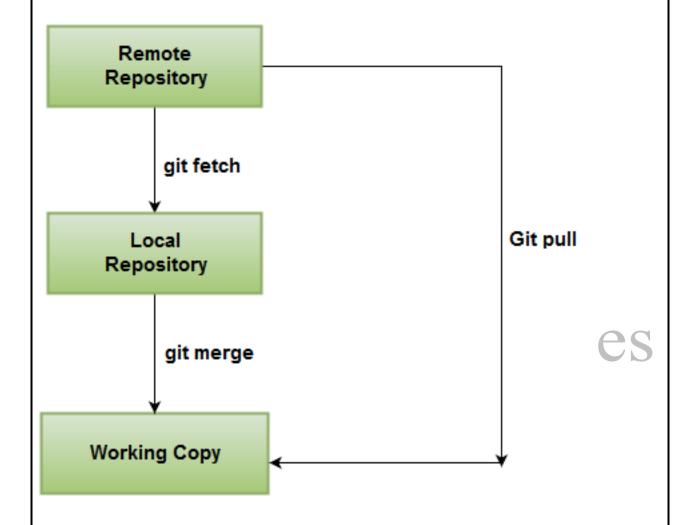

http://mithuntechnologies.com

devopstrainingblr@gmail.com

Git Commands

git pull: It will get the update from git remote repo and will update your local repo as well it will merge with Local working copy also.

So git pull = git fetch + git merge origin/master

git branch -a: It will display all the remote and local branches
git branch -r: It will display all the remote branches.
git config http.sslVerify false: To disable SSL verification for that singular repository
git config --global http.sslVerify false : To disable the SSL verification for Globally (For all
repositories) --> Not suggested way
                                    hnologies
git clone << Git URL>>: To get the code from repository into your local machine.
git log: It will display the commit history.
git log -p -2: which shows the difference introduced in each commit. You can also use -2, which
limits the output to only the last two entries:
git log --stat: If you want to see some abbreviated stats for each commit, you can use the --stat
option.
git rm: Removes files from your index and your working directory so they will not be tracked.
git stash: git stash temporarily shelves (or stashes) changes you've made to your working copy
so you can work on something else, and then come back and re-apply them later on. Stashing is
handy if you need to quickly switch context and work on something else, but you're mid-way
through a code change and aren't quite ready to commit.
